

one row: N elements = C chunks of M

leaf: each of P slices streams
 $\lceil C/P \rceil$ chunks (sort, merge,
rebuild) into an M -wide sorted
window $\approx 2\lceil C/P \rceil$ merge units

level 1

level 2

each edge: ONE M -wide window
(values + indices) over the NoC;
 $P-1$ transfers total --- losers
never leave their slice

root: top- K
(values + indices)

placement: cost-optimal
 $a \times b$ rectangle (8×4 ,
 $P = 32$) on the 13×10
worker grid
